

Time machine won't backup

I'm not robot  reCAPTCHA

Continue

An apple time machine usually backs up on an external drive or wireless to a time capsule. But, if you have a spare Mac, you can turn it into a time machine server. All your other Macs can back up time before it on the network, just as if it were a time capsule. This requires Apple's OS X Server software. Unlike Microsoft's Windows Server, OS X Server is a \$20 app that can be installed on any Mac. You can technically do this without OS X Server, but you don't have to. Supported Method: OS X Server RELATED: How to back up your Mac time and recover files with a time machine Get Apple's OS X server for \$20 from the Mac App Store if you want to do so. Among the many features of OS X Server, it can customize the Mac to function as a Time Machine server. Despite the name, OS X Server is not another operating system - it's just an application that you can install on top of the existing Mac OS X system. This is ideal if you have a spare Mac lying around - or perhaps if you have a Mac desktop you want to use as a centralized server for multiple MacBooks. Install OS X Server on Mac and open the newly installed Server app. Select the time machine under the service on the left side and install the slider in the top right corner on On to turn on the Time Machine server. You will be offered a place on the Mac where you want to store backups. You can also limit individual backups to a certain amount of space to prevent one Mac from hogging all the storage. That's it - you're done if you want to be. You can also add additional backup directions using the box at the bottom of the box, which is useful if you have a few drives that you want to provide as backup seats. For example, you can select multiple external drives that you leave connected to your Mac, or select backup locations on several different internal drives. You can also restrict access to the Time Machine server to certain users. By default, any Mac on the local network can go back to it. Click Change to the right of Permissions, and you can restrict access to certain user accounts. After a few backups you can click on the Backup tab at the top of this control panel to see the backups on the Time Machine server and how much space they take up. You can remove backups from here to manage the space available on your server, too. To actually back up another Mac's time on the Time Machine server, open the Time Machine interface on another Mac on the same local network as your server. You'll see it appear as locations on the drive list, just like Time Capsule devices do. Repeat on every Mac you want to return to the Time Machine server over the network. ANSWER: As you free up the space used by local Time Machine backups on your Mac as usual, the Mac will only back up to the location of the network as long as it is connected to the outlet and charging. If you want it to be charged by battery, click Options Options in the Time Machine interface and activate back up while on the battery checkbox. And remember that this will also only work when you're on the same local network as your Time Machine server. When you're away from this network, your Mac won't back up - aside from creating local backups on your internal store. Unsupported method: Don't do it! This is a supported method that you should use, anyway. There is an unofficial method that involves turning file-sharing on the Mac to create an AFP server (Apple Filing Protocol). The network drive you share should be formatted with the HFS file system. But you don't have to do that. On Mac you want to back out, open the terminal window and run the following command: by default write com.apple.systempreferences.TMShowUnsupportedNetworkVolumes 1 You can open the Time Machine interface on this Mac and it will show any old network drive. Choose a network drive and Time Machine will try to get back to it. Warning: Don't do it! Any problems can cause backup damage. For example, if a network connection falls while backing up a Mac, Time Machine backups may be damaged. Indeed, it's not worth it - spend \$20 for OS X Server and use the officially supported Time Machine server if you want to do so. This is better than ending up with damaged backups. If you don't want to spend \$20, just back up on a connected external drive with Time Machine and skip the backup network. Of course, we're big fans digging around with hidden options and hacking things together. But backups are extremely important. It's not worth the risk of corrupting your backup files - even if it seems to work well for a while, there's always a risk that your backups could become damaged down the line. OS X Server is cheap for server software and is the perfect solution for this. You can always just get an Apple time capsule, of course. You can go back to the built-in storage on the network without the need for an additional Mac to work as a server. Image Credit: Konstantinos Payavlas on Flickr CodeFromThe70s blog has a tutorial to back up your current Windows XP installation on a virtual machine that you can access anytime from your fresh Windows installation, potentially facilitating the process of a new installation. If you need to do something with the software that was on your old system, just download the sucker and do it there. If you're missing some obscure document or data file that's left on your old machine, download the VM and get it. Obviously, for the most used programs you don't want to start a virtual machine every time, You want to get something done, but for those once in a blue-moon effort, switching to a virtual machine can be a lot faster than the hunting and installation program you need. Afraid of re-installing Windows XP? It's CodeFromThe70s.org easy to set up Time Machine, a backup software that comes with every Mac. You just have to point out to your external hard drive and let it do its job. But how do I recover data from Time Machine backups when you need it? There are three ways to do this: use the Time Machine app to recover certain files. Return the entire Mac to the previous backup with macOS Recovery. Migrate your files or user accounts to another Mac with a migration assistant. Here's a rundown of all of these methods, including what to do if your Mac spends a lot of time searching for a Time Machine backup. 1. As you use the time machine to recover specific files Most of the time, you only need to recover one file from the Time Machine. You may have deleted your Time Machine backup by mistake, or you need to return the document to something that it did two weeks ago. If you use Time Machine to create regular backups, you can fix both of these problems with the Time Machine app. Open the document you want to restore, or go to the place where you deleted it in Finder. Then open Time Machine from the App folder using Spotlight to search for it or select Enter Time Machine from the menu bar. When you open Time Machine, it shows all previous versions of your active document. Go back in time, using up and down arrows, or selecting a date on the right side of the screen. Choose the file you want to restore and click the space to view it. When you're sure it's the right version, click Recovery to return the file to the current version of macOS. 2. How to recover everything from a time machine backup when needed, you can restore every file, user account, and settings on your Mac from the previous time machine backup. This is useful if something goes wrong in macOS that you don't know how to fix, or if you want to move all the data to a new Mac. To restore all time machine backups, you need to download to macOS Recovery. This is a hidden section that you can use for: Re-installing the macOS Run Disk Utility to erase or repair your hard drive Get help online using Safari To Restore your Mac using a backup time machine. Obviously we are interested in the fourth option here. Before we can use it, we need to load up in macOS recovery. As you load into macOS Recovery, turn off your Mac completely and then turn it on again, holding cmd and R keys. Hold both keys until you see the launch screen, followed by a macOS Utilities window. If that doesn't work, try downloading macOS Online Recovery instead of holding the Cmd and option R while your Mac is on. A rotating globe should appear while your Mac downloads macOS Recovery from the Internet. Old Macs running OS X Snow Leopard or earlier may have to download to the Recovery section instead of restoring macOS. Turn off the Mac and then hold the option until it's turned on. Choose the Recovery section next to the launch drive. How to back up a time machine from macOS Recovery from the macOS Utilities window, tap Recovery from the Time Machine and select a backup drive. Keep an eye out for To choose the date and time to recover, then choose your Mac's hard drive as your destination. Click Recovery and Wait for Time Machine to copy all files on your Mac. It may take some time, but when it's finished, everything will look and feel just like it did when you did the backup. 3. Migrate Files or user accounts in another mac Migration Assistant is Apple's tool for transferring files or user accounts from one Mac to another. The Migration Assistant can use a time backup machine to import selected files or user accounts, rather than to restore the entire backup. The brand-new Mac encourages you to use Migration Assistant while you're tuning in. You can also open a migration assistant from the Utility folder in the apps to transfer data to the Mac you already want. Keep an eye out for tips in Migration Assistant to transfer information from your Mac, back up Time Machine, or launch a drive. Select a backup drive and select the date and time you want to move files from. You can transfer the following data via Migration Assistant: Computer Apps and Network Settings Documents and Data, including user accounts and specific folders What if macOS is stuck searching for a backup time machine? Whether you're using Time Machine to recover all backups or transfer a single file, you may be caught up in macOS in search of backups. This happens when your Mac can't properly communicate with the backup drive. Sometimes macOS spend hours looking for Time Machine backups without success. If this happens to you, the next steps below should help fix it. From the bar menu, go to Apple's menu, about this Mac's software update. Download and install the latest version of macOS for your Mac, and then try looking for Time Machine backups again. Step 2: Throw out and reconnect the backup drive to your Mac Open Finder and tap the ejection icon next to the time machine backup drive in the left sidebar. Once the drive is ejected, disable the USB or Thunderbolt cable and check it for signs of damage or debris. Wait 30 seconds and then plug in the drive. Try using another USB port or Thunderbolt and cable if you have one available. If you're using an AirPort time capsule or another NAS drive to back up Time Machine, disconnect it from the network and then restart the drive and connect it to the network again. Step 3: Restart the Mac usage search to re-extract the Time Machine backup drive, then go to the Apple menu to reboot the Mac. If macOS still spends a lot of time searching for Time Machine backups after Connect the drive, contact Apple support for more help. Don't delete the time machine to back up after recovering from the recovery of what you need from backing up the time machine, it's tempting to send that backup to the shopping cart. We know what you think: you don't need it anymore, so you have to make space for new backups. But that's not a good idea! Not only is there no need to delete backups--Time Machine automatically removes old old ones When it needs more space-- but Time Machine backups get stuck in the trash if you don't remove them properly. Save yourself the hassle and leave those backups alone. How do I fix the 'DNS Server Not Responding' bug to get back online looking at a DNS error? Here's how you fix it and go back online.
